User manual

Gain Manager library software expansion for STM32Cube

Introduction

The Gain Manager (GAM) library user manual describes the software interface and requirements for the integration of the module into a main program like the audio STM32Cube expansion software and provides a rough understanding of the underlying algorithm.

The GAM library is used to apply several gain attenuations depending on channel number of audio signal.

The GAM library is part of the following firmware packages:

- X-CUBE-AUDIO-F4
- X-CUBE-AUDIO-L4
- X-CUBE-AUDIO-F7

List of figures

1 Module overview

1.1 Algorithm function

The GAM module allows the user to modify digitally the volume of the input signal in the [-80;0] dB range, with a granularity of 0.5 dB.

1.2 Module configuration

The GAM module can handle mono, stereo and multichannel interleaved (up to eight channels) 16-bits and 32-bits I/O data.

Several versions of the module are available:

- lib_gam_m4.a: 16 bits input/output buffers version, it runs on any STM32 microcontroller featuring a core with Cortex®-M4 core.
- lib_gam_32b_m4.a: 32 bits input/output buffers version, it runs on any STM32 microcontroller featuring a core with Cortex®-M4 core.
- lib_gam_m7.a: 16 bits input/output buffers version, it runs on any STM32 microcontroller featuring a core with Cortex®-M7 core.
- lib_gam_32b_m7.a: 32 bits input/output buffers version, it runs on any STM32 microcontroller featuring a core with Cortex®-M7 core.

1.3 Resources summary

Table 1 contains Flash, stack, RAM memory and frequency (MHz) requirements of the module.

Table 1. Resources summary(1)

Version	Core	Flash code (.text)	Flash data (.rodata)	Stack	Static RAM	Dynamic RAM	Frequency (MHz)
16 bits I/O stereo	M4	1604 Bytes	8 Bytes	44 Bytes	120 Bytes	1 Byte	2.4
	M7	**1580 Bytes**					**1.3**
16 bits I/O multichannel 3.1	M4	1604 Bytes					4.4
	M7	**1580 Bytes**					**2.4**
32 bits I/O stereo	M4	1604 Bytes					2.6
	M7	**1580 Bytes**					**1.7**
32 bits I/O multichannel 3.1	M4	1604 Bytes					4.6
	M7	**1580 Bytes**					**3.0**

1. Data for M7 core are in bold type when different from those of M4.

Note: Footprints on STM32F7 are measured on boards with stack and heap sections located in DTCM memory.

Note: Dynamic RAM is the memory that can be shared with other process running on the same priority level. This memory is not used from one frame to another by GAM routines.

2 Module Interfaces

Two files are needed to integrate the GAM module. lib_gam_XXX_mY.a library and the gam_glo.h header file which contain all definitions and structures to be exported to the software integration framework.

Note: The audio_fw_glo.h file is a generic header file common to all audio modules; it must be included in the audio framework.

2.1 APIs

Six generic functions have a software interface to the main program:

- gam_reset
- gam_setParam
- gam_getParam
- gam_setConfig
- gam_getConfig
- gam_process

Each of these functions is described in the following sections.

2.1.1 gam_reset function

This procedure initializes the static memory of the GAM module, and initializes static and dynamic parameters with default values.

```
int32_t gam_reset(void *static_mem_ptr, void *dynamic_mem_ptr);
```

Table 2. gam_reset

I/O	Name	Type	Description
Input	static_mem_ptr	void *	Pointer to internal static memory
Input	dynamic_mem_ptr	void *	Pointer to internal dynamic memory
Returned value	–	int32_t	Error value

This routine must be called at least once at initialization time, when the real time processing has not started.

2.1.2 gam_setParam function

This procedure writes module's static parameters from the main framework to the module's internal memory. It can be called after the reset routine and before the start of the real time processing. It handles the static parameters, i.e. the parameters with the values which cannot be changed during the module processing.

```
int32_t gam_setParam(gam_static_param_t *input_static_param_ptr, void
*static_mem_ptr);
```

Table 3. gam_setParam

I/O	Name	Type	Description
Input	input_static_param_ptr	gam_static_param_t*	Pointer to static parameters structure
Input	static_mem_ptr	void *	Pointer to internal static memory
Returned value	–	int32_t	Error value

2.1.3 gam_getParam function

This procedure gets the module's static parameters from the module internal memory to the main framework. It can be called after the reset routine and before the start of the real time processing. It handles the static parameters, i.e. the parameters with values which cannot be changed during the module processing.

```
int32_t gam_getParam(gam_static_param_t *input_static_param_ptr, void
*static_mem_ptr);
```

Table 4. gam_getParam

I/O	Name	Type	Description
Input	input_static_param_ptr	gam_static_param_t *	Pointer to static parameters structure
Input	static_mem_ptr	void *	Pointer to internal static memory
Returned value	–	int32_t	Error value

2.1.4 gam_setConfig function

This procedure sets the module's dynamic parameters from the main framework to the module internal memory. It can be called at any time during the module processing (after the reset and setParam routines).

```
int32_t gam_setConfig(gam_dynamic_param_t *input_dynamic_param_ptr, void
*static_mem_ptr);
```

Table 5. gam_setConfig

I/O	Name	Type	Description
Input	input_dynamic_param_ptr	gam_dynamic_param_t *	Pointer to dynamic parameters structure
Input	static_mem_ptr	void *	Pointer to internal static memory
Returned value	–	int32_t	Error value

2.1.5 gam_getConfig function

This procedure gets the module's dynamic parameters from the internal static memory to the main framework. It can be called at any time during processing (after the reset and setParam routines).

```
int32_t gam_getConfig(gam_dynamic_param_t *input_dynamic_param_ptr, void
*static_mem_ptr);
```

Table 6. gam_getConfig

I/O	Name	Type	Description
Input	input_dynamic_param_ptr	gam_dynamic_param_t *	Pointer to dynamic parameters structure
Input	static_mem_ptr	void *	Pointer to internal static memory
Returned value	–	int32_t	Error value

2.1.6 gam_process function

This procedure is the module's main processing routine. It should be called at any time, to process each frame.

```
int32_t gam_process(buffer_t *input_buffer, buffer_t *output_buffer, void
*static_mem_ptr);
```

Table 7. gam_process

I/O	Name	Type	Description
Input	input_buffer	buffer_t *	Pointer to input buffer structure
Output	output_buffer	buffer_t *	Pointer to output buffer structure
Input	static_mem_ptr	void *	Pointer to internal static memory
Returned value	–	int32_t	Error value

This process routine can run in place, that is the same buffer can be used for input and output.

2.2 External definitions and types

Some types and definitions have been defined to facilitate the integration in the main frameworks.

2.2.1 Input and output buffers

The GAM library is using extended I/O buffers which contain, in addition to the samples, some useful information on the stream such as the number of channels, the number of bytes per sample and the interleaving mode.

An I/O buffer structure type, as described below, must be followed and filled in by the main framework before each call to the processing routine:

```
typedef struct {
    int32_t       nb_channels;
    int32_t       nb_bytes_per_Sample;
    void          *data_ptr;
    int32_t       buffer_size;
    int32_t       mode;
} buffer_t;
```

Table 8. Input and output buffers

Name	Type	Description
nb_channels	int32_t	Number of channels in data: 1 for mono, 2 for stereo, 4 for 3.1
nb_bytes_per_Sample	int32_t	Dynamic data in number of bytes (2 for 16-bit data, 4 for 32-bit)
data_ptr	void *	Pointer to data buffer (must be allocated by the main framework)
buffer_size	int32_t	Number of samples per channel in the data buffer
mode	int32_t	Buffer mode: 0 = not interleaved, 1 = interleaved

2.2.2 Returned error values

Possible returned error values are described below:

Table 9. Returned error values

Definition	Value	Description
GAM_ERROR_NONE	0	OK - No error detected
GAM_UNSUPPORTED_VOLUME	-1	Volume setting is outside [-80; 0] db range
GAM_UNSUPPORTED_MUTE_MODE	-2	Multi mode is not supported
GAM_UNSUPPORTED_NUMBER_OF_BYTEPERSAMPLE	-3	Input data is neither 16-bit nor 32-bit value
GAM_UNSUPPORTED_INTERLEAVING	-4	Input data is stereo / not interleaved
GAM_UNSUPPORTED_MULTICHANNEL	-5	Number of channels is not supported
GAM_BAD_HW	-6	The library is not used with the right hardware

2.3 Static parameters structure

There is no static parameter to be used. For the compatibility with other structures, the static parameter structure contains a dummy field.

```
struct gam_static_param {
    int8_t   empty;
};
typedef struct gam_static_param gam_static_param_t;
```

Table 10. Static parameters structure

Name	Type	Description
empty	int8_t	Dummy field, just required to have a non-empty structure

2.4 Dynamic parameters structure

Three dynamic parameters can be used.

```
struct gam_dynamic_param {
    int16_t   target_volume_dB[8];
    int16_t   mute[8];
};
typedef struct gam_dynamic_param gam_dynamic_param_t;
```

Table 11. Dynamic parameters structure

Name	Type	Description
target_volume_dB[8]	int16_t	Volume dB input value, in 1/2 dB steps, for each of the 8 different channels. Example:” -12,-12,-12,-12,-13,-13,-13,-13” means the first 4 channels will get a target output volume of -6 dB, the 4 others a target volume of -6.5 dB
mute[8]	int16_t	1 = enable mute, 0 = disable, for each of the 8 different channels.

3 Algorithm description

3.1 Processing steps

The GAM algorithm is composed of one main processing block (called gain application block), that attenuates the signal, depending on the target volume value set among the dynamic parameters.

It can be different for each channel.

Every target volume value change is applied with smooth transition to the output signal.

3.2 Data formats

The GAM module supports fixed point mono and stereo multichannel interleaved 16-bits and 32-bits input data. It can work independently of the frame size and the input signal sampling rate.

However it is recommended to avoid selecting very short frame size (i.e. lower than 2 ms), in order to prevent “plops” on transitions due to too short ramp up/down of the volume.

The module delivers output data, following the same interleaved pattern and 16-bits or 32-bits resolution, as the input data.

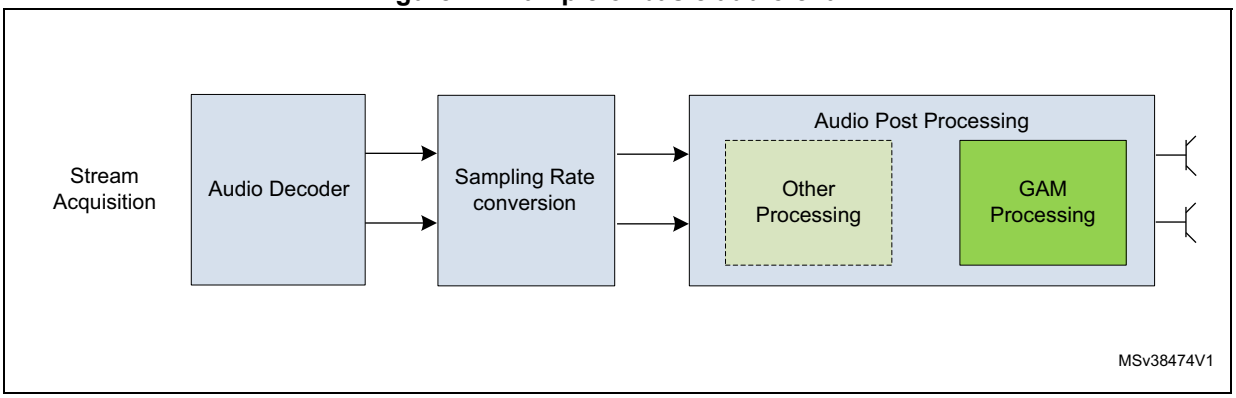
4 System requirements and hardware setup

GAM libraries are built to run either on a Cortex® M4 or on a Cortex® M7 core, without FPU usage. They can be integrated and run on corresponding STM32F4/STM32L4 or STM32F7 family devices. There is no other hardware dependency.

4.1 Recommendations for an optimal setup

It is advised to execute the GAM library close to the audio DAC to avoid decreasing the Signal to Noise Ratio (SNR) before other post processing modules execution. Refer to *Figure 1: Example of basic audio chain*

Figure 1. Example of basic audio chain



4.1.1 Module integration example

An integration framework running on STM32F411VE discovery board, for X-CUBE-AUDIO-F4, is provided with GAM libraries. Please refer to this code in “fw_integ” folder as an integration example.

Below are explained important steps to follow GAM integration, based on provided code.

Memory allocation

First of all, all the memory used by the module must be allocated:

```
pGamStaticMem = malloc(gam_static_mem_size);
pGamDynamicMem = malloc(gam_dynamic_mem_size);
/* I/O buffers allocation and settings */
input_buffer.data_ptr = malloc(pDecoderStruct->PacketSize);
input_buffer.nb_bytes_per_Sample = num_bytes_per_sample;
input_buffer.buffer_size = frame_size_input;
input_buffer.mode = interleaving_mode;
input_buffer.nb_channels = num_channels;
output_buffer.data_ptr = malloc(pEncoderStruct->PacketSize);
output_buffer.buffer_size = frame_size_output;
output_buffer.mode = input_buffer.mode;
output_buffer.nb_bytes_per_Sample = input_buffer.nb_bytes_per_Sample;
```

```
output_buffer.nb_channels = input_buffer.nb_channels;
```

Module initialization

Once the memory is allocated, some routines must be called to initialize the GAM module static memory.

- The *gam_reset()* routine should be called at least once, before the audio processing starts.
- The *gam_getParam()* and *gam_setParam()* routines are not used here since currently there is no static parameter.

```
/* Enables and resets CRC-32 from STM32 HW */
__HAL_RCC_CRC_CLK_ENABLE();
CRC->CR = CRC_CR_RESET;

/* GAM effect reset */
error = gam_reset(pGamStaticMem, pGamDynamicMem);
if (error != OMNI2_ERROR_NONE)
{
return (error);
}
```

Module execution

Now that the hardware is configured and the GAM module initialized and configured, the run time process can start.

At each new frame, the input buffer data must be filled and GAM processing routine can be called. *gam_setConfig()* and *gam_getConfig()* routines are used to extract/set dynamic parameters.

```
do
{
     :
     :
/* GAM dynamic parameters that can be updated here every frame if required
*/
      gam_dynamic_param.target_volume_dB[0] = -12; /* Target dB volume in
1/2dB steps*/
      gam_dynamic_param.target_volume_dB[1] = -12;
      gam_dynamic_param.target_volume_dB[2] = -12;
      gam_dynamic_param.target_volume_dB[3] = -12;
      gam_dynamic_param.target_volume_dB[4] = -12;
      gam_dynamic_param.target_volume_dB[5] = -12;
      gam_dynamic_param.target_volume_dB[6] = -12;
      gam_dynamic_param.target_volume_dB[7] = -12;
      gam_dynamic_param.mute[0] = 0; /* Mute Flags for all channels*/
      gam_dynamic_param.mute[1] = 0;
      gam_dynamic_param.mute[2] = 0;
      gam_dynamic_param.mute[3] = 0;
      gam_dynamic_param.mute[4] = 0;
```

```
        gam_dynamic_param.mute[5] = 0;
        gam_dynamic_param.mute[6] = 0;
        gam_dynamic_param.mute[7] = 0;
        error = gam_setConfig(&gam_dynamic_param, pGamStaticMem);
        if (error != GAM_ERROR_NONE)
        {
          return (error);
        }
        /* GAM effect processing */
        error = gam_process(pInputBuffer, pOutputBuffer, pGamStaticMem);
        if (error != GAM_ERROR_NONE)
        {
          return (error);
        }:
       :
}
```

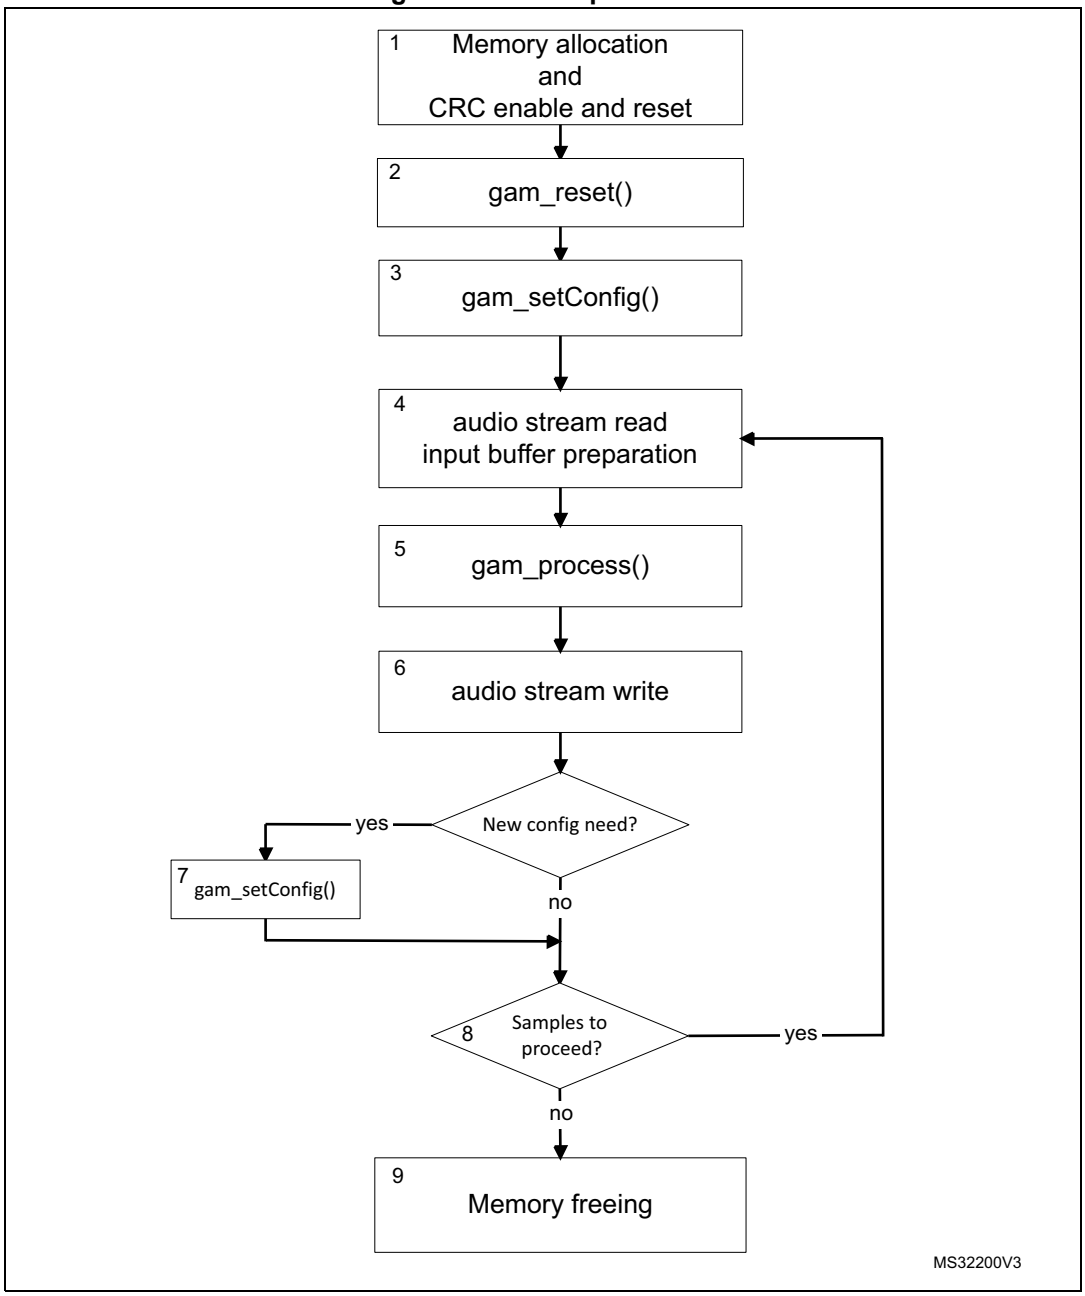
Memory freeing

At the end of task execution, memory allocated for GAM module can be freed.

```
free(input_buffer.data_ptr);
free(output_buffer.data_ptr);
free(pGamStaticMem);
free(pGamDynamicMem);
```

4.1.2 Module integration summary

Figure 2. API call procedure



1. As explained above, GAM static and dynamic structures have to be allocated, as well as input and output buffers. Furthermore, as GAM library runs on STM32 devices, CRC HW block must be enable and reset.
2. Once the memory is allocated, the call to gam_reset() function initializes the internal variables.
3. Once the dynamic parameters are updated, the gam_setConfig() routine is called to send the dynamic parameters from the audio framework to the module.
4. The audio stream is read from the proper interface and input_buffer structure has to be filled accordingly to the stream characteristics (number of channels, sample rate, interleaving and data pointers). Output buffer structure has to be set as well.
5. Main processing routine is called to apply the effect.
6. The output audio stream can now be written in the proper interface.

7. If needed, the user can set new dynamic parameters and call the gam_setConfig() routine again, to update the module configuration.
8. If the application is still running and has new input samples to proceed, then it goes back to step 4, else the processing loop is over.
9. Once the processing loop is over, the allocated memory has to be freed.

5 How to run and tune the application

Once the module is integrated into the audio framework to play samples at 48 kHz, launch the Audio player and, if there is no sampling rate conversion available, choose a .wav or .mp3 file with a 48 kHz sampling frequency.

The GAM “target_volume_dB” dynamic parameter represents the volume asked by the user, in 0.5 dB steps. The volume change is applied smoothly to avoid audible artifacts. It can be applied independently on each channel of output signal.

The GAM “mute” dynamic parameter mutes the output when set to 1 or has no influence on input signal when set to 0. When enabled, it allows muting the signal smoothly over a frame, avoiding audible artifacts. It can be applied independently on each channel of output signal.

Please refer to the provided integration framework running on STM32F411VE discovery board. The user should refer to the provided integration framework running on STM32F411VE discovery board for X-CUBE-AUDIO-F4, STM32L476VG discovery board for X-CUBE-AUDIO-L4 and STM32F746NG discovery board for X-CUBE-AUDIO-F7. This example of GAM library integration builds on IAR v7.40 tool chain. It gets stereo 48 kHz .wav input file from PC host, transfers it via semi-hosting using ST-Link, decodes and applies GAM algorithm effect, re-encodes it as .wav file and transfers output file to the PC.

Consumed MHz are also monitored and can be extracted via *CycleStats_Cumul* structure. They are also printed on IAR embedded I/O terminal.
